Conclusion and Inference

We can conclude from above data:

i) On basis of time taken to execute:

a) Changing O0, O1, O2, O3 we get most optimal result in O3.

For a particular N Matmul2 performs better than Matmul1 and Matmul3 performs better than both. Faster run-time for matmul2 than matmul1 refers that matmul2 the inner most loop has to store and perform scalar vector multiplication while in matmul1 it has to perform product of 2 vectors. Matmul3 gives best ^{result} due to multiplication on blocked matrix.

Computation intensity of blocked matrix = $q \cdot 2n/N$ (Number of blocks).

Form a particular matrix multiplication doubling the dimensions increases the run time by approximately 8 times as the cost of matrix multiplication is approx. $O(n^3)$.

ii) Cache Miss:

Among the three different multiplication approaches the row block matrix gives the least execution time. Total number of instructions, the total L1 cache miss, the total L2 cache miss is tableted above with total number of instructions executed and total number of cycles. Total number instructions do not change significantly with dimensions of block size.

For matmul1 and matmul2 the L1 and L2 cache misses increase greatly with the increase in dimension of matmul3 the cache miss increases significantly with dimension size, however show a slight variation with increasing size.
